

Simplifies creating edge functions on deno

Created via a function file in an `netlify/edge-functions` directory at the root of your project (a custom directory can be configured via the `netlify.toml`). You must declare which route the function applies to in the configuration (does not default to every route like middleware).

Key limitations:

- Number of invocations depends on the pricing plan (free plan includes 3 million invocations a month)
- Beta doesn't work with Netlify's A/B testing solution.

Edge functions provide geolocation information in the `context.geo` variable.

Netlify also has a Next.js Advanced Middleware package that includes things like modifying headers and content [source](#).
